Objectives

- To understand built-in data sequence types such as Lists, Sets, Tuples and Dictionaries.
- To understand their use and advantages.
- To understand iterations and constructs that support sequences.
- To learn the different operations that could be performed on these types.

Lists

- Lists are a collection of data elements arranged sequentially.
- They are mutable in nature, in that they can be appended to, and data removed from.
- Lists are enclosed by a pair of squared brackets '[]'
- Lists in Python are heterogeneous. A list can contain any different type of data.
- Lists are especially good for keeping track of things that might change.
- A list could be created by saying [] or list().

Creating a List of Lists

A list could be created with other lists as elements of it.

```
>>> cities = [ 'Chicago', 'San_Francisco', 'New_York' ]  
>>> metros = [ 'Dallas', 'Las_Vegas', cities ]  
[ '8', '11', '2017' ]
```

- Changing the cities list here modifies the metros list as well.
- This is because, cities is just a reference to the block of memory containing "cities list" and that is being reflected in the metros list.

Data Type Conversions in Lists

Converting a string to a list as easy as `list('Python')`

A string could also be converted into a List by using the `split()` method by splitting at a character of our choice.

```
>>> birthday = '8/11/2017'
>>> birthday.split('/')
['8', '11', '2017']
```

A list can be converted to a String using `join()` as follows:

```
>>> list = ['I', 'love', 'Python']
>>> ' '.join(list)
'I love Python'
```

Common List Operations

The following are the common operations in List.

- Adding elements to the list using add, append and insert.
- Indexing and Slicing.
- Modifying the list using indexing and Slicing techniques.
- Concatenating Lists.
- Removing items from the list using "del" remove and pop.
- Determining the membership of an item and counting the number of items.
- Searching and Sorting the list.

Tuples

Similar to lists, tuples are sequences of arbitrary items.

- Tuples are is the immutable collection sequence type in Python.
- Tuples can't be modified using add, delete, or changing of items after the tuple is defined. A tuple is this a constant list.
- A tuple can be created using ().
- Notice that a list can be created as follows "list()".

Tuple Unpacking

- Multiple variables can be assigned at one go using Tuples in Python
- This underlying nature has a bigger advantage in Python is a few operations such as variable swapping.
- In other programming languages, particularly statically-typed language, it is more complicated than how it's done in Python.
- Without the use of a temporary variable, unlike in other languages, in Python, two variables can be swapped as follows: `a,b = b,a`

Summary

- We understood what sequences are in Python.
- We extensively experimented with Python's sequential data types such as Lists and Tuples.
- We learned the difference between these two sequence types and how they help us in different situations.
- We understood and worked with the different methods that these two structures provide.
